Abstract: Large number of documents is grouped according to their similarities. The Text Mining methods have been proposed to solve the problem by automatically classifying text documents, mainly in English. But this method has some limitations when dealing with non-English language texts, e.g., Chinese research proposals. An ontology based text mining approach is to cluster the documents based on their similarities. For ontology making in text documents, the clustering algorithm is need to be applied. This paper focuses on two clustering techniques SOM and DVA for clustering documents based on their similarities. SOM and DVA algorithms are applied after the preprocessing process with documents such as Stop Word Removal, Stemming. DVA includes Vector Dimension Reduction also. The proposed Ontology based text mining technique is efficient and effective in terms of time, reliability and quantity. DVA out performs than SOM in terms of all the factors.

Keywords: Text Mining, Ontology, OTMM, Clustering, SOM and DVA Algorithm

I. INTRODUCTION

In the fast developing information explosion era, much of the knowledge available is stored as text. It is not surprising, therefore, that data mining (DM) and information retrieval (IR) from text collections (text mining) has become an active and exciting research area in computer applications [1]. The purpose of Text Mining is to process unstructured (textual) information, extract meaningful numeric indices from the text, and, thus, make the information contained in the text accessible to the various data mining (statistical and machine learning) algorithms. Information can be extracted to derive summaries for the words contained in the documents or to compute summaries for the documents based on the words contained in them. Hence, we can analyze words, clusters of words used in documents, etc., or one could analyze documents and determine similarities between them or how they are related to other variables of interest in the data mining project. Clustering or segmentation of data is a fundamental data analysis step that has been widely studied across multiple disciplines for over 40 years. Clustering text documents into different category groups is an important step in indexing, retrieval, management and mining of abundant text data on the Web or in corporate information systems.

In section 2 Literature survey is discussed. Our proposed algorithm is explained in section 3. Section 4 deals with performance analysis using line chart with SOM and DVA algorithms. Conclusion is in section 5.

II. LITERATURE SURVEY

An Ontology based text mining method discussed in [2]. The R&D project selection [3], how the project selection and development can be made is described. The text mining application is discussed in [4]. The Information Retrieval and Information Extraction [5] is to extract the documents for users need.

Different methods are used for measure the performance of ontology based information extraction. The Balanced Distance Metric (BDM) is described [6]. The survey performed here is [7] different component based information extraction rules are categorized. The extraction from the large amount of data using RDBMS is discussed in [1]. The Ontology based text mining framework is used to increase the effectiveness of the project, which is described in [8].

The Ontology based text mining method and Information Extraction is used for biological domain is explained in [9]. In pattern discovery for text mining [10] and the Ontology based concept weighing [11], different concepts are compared. The Ontology based text mining techniques uses different clustering methods. The clustering methods to cluster the text documents are discussed in [12]. The ontology based applications such as network based P2P fuzzy logic techniques and the approach of automatic construction of hypertexts in text mining are explained in [13, 14]. The different aspects of semantic web [15] and the learning features are discussed. Like the previous one, [16] this book also teach the researchers and developers who are in ontology based applications development and in E-Learning. Several techniques in text categorization and the learning rule algorithms are discussed [17].

III. PROPOSED ALGORITHM

To solve the aforementioned problems, an Ontology-based TMM (OTMM) is proposed. An ontology is a knowledge repository in which concepts and terms are defined as well as relationships between these concepts [18]. Some of the reasons to develop ontology

a. To share common understanding of the structure of information among people or software agents
b. To enable reuse of domain knowledge
c. To make domain assumptions explicit
d. To separate domain knowledge from the operational knowledge
e. To share common understanding of the structure of information among people or software agents
f. To share common understanding of the structure of information among people or software agents

This section is discussed as follows. In Phase 1 text documents collection process is explained. In Phase 2 preprocessing process such as stop word removal and stemming process is discussed. In Phase 3 grouping process is explained. In Phase 4 and 5 the importance of Ontology making and clustering by SOM and DVA algorithms are discussed. For algorithm making the parameter usage [19] is discussed. The proposed architecture is shown in figure 1.

A. Phase 1: Collection Of Text Documents:

The text documents are collected for the mining process. There is no limitation for collecting the documents. They are placed in a particular directory. Because every time we choose the file path and select any document for text mining process.

B. Phase 2: Preprocessing Process:

Step1: Stop word removal

A stop word is a commonly used word (such as “the”) that a search engine has been programmed to ignore, both when indexing entries for searching and when retrieving them as the result of a search query. When building the index, most engines are programmed to remove certain words from any index entry. The list of words that are not to be added is called a stop list. Stop words are deemed irrelevant for searching purposes because they occur frequently in the language for which the indexing engine has been tuned. In order to save both space and time, these words are dropped at indexing time and then ignored at search time. Table 1 shows the sample stop words, and Figure 2 shows the sample stop word removal process. After choosing the file the list of stop words removed are shown in the list box.

<table>
<thead>
<tr>
<th>Table 1. The List of sample stop words</th>

<tbody>
<tr>
<td>a  an  and  are  as  at  be  by  for  from</td>
</tr>
<tr>
<td>has  he  in  is  its  of  on  that  the</td>
</tr>
<tr>
<td>to  was  were  will  with</td>
</tr>
</tbody>
</table>

Figure 2. Removal of Stop Words

Step 2: Stemming Process:

Stemmers used to reduce a word to its stem or root form. Thus, the key terms of a query or document are represented by stems rather than by the original words. This not only means that different variants of a term can be conflated to a single representative form – it also reduces the dictionary size, that is, the number of distinct terms needed for representing a set of documents. A smaller dictionary size results in a saving of storage space and processing time. In Figure 3 sample stemming process is shown.

Figure 3. Stemming Process

C. Phase 3: Grouping Process:

After completing the preprocessing steps such as stop word removal and stemming process the words are grouped according to their similarity.

D. Phase 4: Ontology Making:

The creation of domain Ontology’s is also fundamental to the definition and use of an enterprise architecture framework. Pragmatically, a common ontology defines the vocabulary with which queries and assertions are exchanged among agents. Ontological commitments are agreements to use the shared vocabulary in a coherent and consistent manner. The agents sharing a vocabulary need not share a knowledge base; each knows things the other does not, and an agent that commits to Ontology is not required to answer all
queries that can be formulated in the shared vocabulary. The Ontology maker is shown in Fig. 4.

E. Phase 5: Clustering:

Clustering usually groups keywords of documents into clusters and constructs ontology by selecting representative concepts from each cluster. Cluster analysis as such is not an automatic task, but an iterative process of knowledge discovery or interactive multi-objective optimization that involves trial and failure. It will often be necessary to modify data preprocessing and model parameters until the result achieves the desired properties. Sample clustering of documents is shown in Fig. 5.

IV. PERFORMANCE EVALUATION

The Core i5 processor is used. For system configuration, windows 7 operating system is used. The problem is done using the application server Visual Studio 2007. The front end C#.net and the Back end SQL Server is used.

A. Time Based Frequency:

Here, the time needed to process the number of documents by SOM and DVA algorithms are analyzed and the results are shown in Fig. 6. For analyzing the quantitative data[20], if the large amount of data from the two different algorithms are used the chart and the axis defined values are explained.
B. **Reliable Documents:**

Reliability of retrieved documents can be made by using the number documents and the frequency measurement. The SOM and DVA algorithms are compared using the line chart shown in Figure 7. In this Figure 7 the reliability of retrieved documents are analyzed.

C. **SOM And DVA Factors:**

Table 2 shows the factors according to which the SOM and DVA algorithms performances are compared in our work.

<table>

V. **CONCLUSION**

Thus an Ontology based text mining approach is to cluster the documents based on their similarities. This method is systematic, efficient and effective for clustering the documents. In this work the collected documents are preprocessed by stopword removal and stemming process. The preprocessed details are grouped then the documents are clustered using SOM and DVA algorithms. The SOM and DVA algorithms performances are compared against time based frequency and reliability of retrieved documents. We proved that DVA outperforms then SOM. Future work is planned to compare the performance of document clustering when various similarity measures and clustering algorithms are combined with ontology features of documents. The Future work suggested that there is a need to compare the results of manual classification to Systematic classification.
