# WEB PAGE ANTICIPATION SYSTEM USING MARKOV MODEL

Shivangi Sorout Department of computer science & Application Maharishi Dayanand University (M.D.U) Rohtak, Haryana Dr. Balkishan (Assistant Professor) Department of computer science & Application Maharishi Dayanand University (M.D.U) Rohtak Haryana

*Abstract:* In the era of digital world, Information can be accessed with the help of Internet on the World Web. Due to the enormous growth of digital information, the limited bandwidth of the network is not utilized in an efficient way. With the help of this "Web P age Anticipation System", we are trying to get rid of this problem. It provides us framework to incorporate the usage of pre-fetching mechanism, Clustering, Markov Model and Prediction Architecture. This framework allows us to anticipate the web page in advance with the help of user's currently accessed web page.

Keywords: com Web page anticipation, Pre-fetchimg Clustering, Markov model, Users sessions

## **1. INTRODUCTION**

Owing t o t he e normous growth o f W orld W ide Web, congestion and overloading of server occurs. Due to problems incurred by the server in managing large information, latency of c ommunication channel is s ubstantially r educed. V arious techniques for latency reduction are web catching, pre-fetching and preopening. Need of this web page anticipation system is required in the er a of e-commerce digital w orld where every transaction is depended only on the efficiency of how fast we are able to accesses the required web page within the particular time s lot. R esearchers us e different ki nd oft echniques comprising M arkov M odel f or ne xt w eb pa ge anticipation, clustering and prediction A rchitecture. F or im plementing t his web p age a nticipation m odel, na vigational be havior of th e current users is stored in the web log files.

After the i dentification of the navigational b ehavior of current us ers, C lustering is performed. Clustering is the main ingredient us ed in the exploratory data mining and commonly used in the statistical data analysis. Main task of clustering is to segregate the group of objects into different groups so that all objects in the one particular group are of similar nature. Scope of clustering is wide and u sed in the many fields like machine learning, image analysis, information retrieval, bioinformatics, data c ompression and c omputer g raphics. Clustering models used in the Clustering are connectivity models, centroid based model (k-means algorithm), distribution model expectation-maximization model) and density model.

When the Clusters are formed we have to use the prediction algorithm to predict the next possible states. After that Markov model is a pplied on the clustering s ets. Markov model is a stochastic m odel w hich i s u sed f or t he designing the continuously c hanging s ystem i n va riable time p eriod a t different time s lots. In this model f uture s tate is depend n ot only on the current state but also on the previous states covered. In the Markov model we have to train the model by estimating the transition probability which is denoted by:

Aij = P(Q(t+1)=Si | Qt=Sj)

Where, Aij is the probability of going to the new state Si at time t+1 from state Sj at time t.

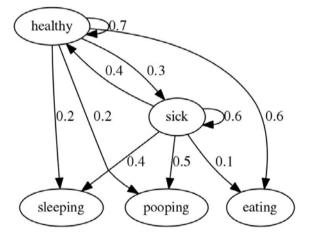

Figure1. Example: Markov Model States and their Transition Probability

The first order Markov model provides us a simple way of to accumulate sequential dependence, however it does not take the aspect of l ong t erm m emory web n avigational behavior. Higher order M arkov m odel are u seful for t he prediction of navigational path. But with the increase of order of the Markov model subsequently there will be exponential i ncrease in the complexity of state space. In turn we require the huge amount of t raining d ata. A s t he n umber o f s tates increase, s ystems which n eeds to predict f ast t heir p rediction a ccuracy is plummeted to large extent. So the need of the hour is to have that kind of system which predict fast with enhanced accuracy.

#### 2.RELATED WORK

The review of past investigation serves as a guide to the researchers as it av oids duplications in the field. The knowledge of what h as al ready b een done in the a rea of investigation regarding the methods used for data is important. Research in any field implies a step ahead in exploration of the unknown. Any researcher to be able to take this step should be adequately prepared for it. One such preparation is gathering of

knowledge of much has already been done in the given field. A step t owards unknown c an only be t aken after the review of literature and r esearches d one in that ar ea. Any research without s uch a review is likely to be a building without foundation. Thus, t he review o fr elated l iterature i s an indispensable step in research.

Yang et al. (2004) studied different association rule based methods for web request prediction. The association rules for web access prediction involve dealing with too many rules and it is not easy to find a suitable subset of rules to make accurate and reliable predictions. F ive di fferent r epresentations o f association rules are: S ubset rules, S ubsequence rules, Latest subsequence rules, Substring rules and Latest substring rules. The au thor c oncerned the precision of these f ive as sociation rules r epresentations using d ifferent selection methods, t he latest substring rules were proven to have the highest precision with decreased number of rules [1].

Liu et al. (1998) introduced a customized marketing based on the web approach using a combination of clustering and association rules. The a uthor collected information a bout customers using forms, W ebs erver log files and cookies. It categorized customers a ccording to the information collected. Since k-means clustering algorithm works only with numerical data, the authors us ed PAM (Partitioning a round M edoids) algorithm to cluster data using categorical scales. Then perform association rule techniques on each cluster [2].

Kim e t a l. (2004) introduced c ombination of a ll t hree models t ogether. It i mproves the performance of Markov model, sequential as sociation rules, as sociation r ules a nd clustering b y combining a ll t hese m odels t ogether. For instance, Markov model is used first. If MM cannot cover an active session or a state, sequential association rules are used. If sequential as sociation rules cannot cover the state, as sociation rules a re used. I f association r ules c annot cover t he s tate, clustering algorithm is applied. The a uthor's w ork im proved recall and it did not improve the Web page prediction accuracy [3].

Vakali et al. (2003) categorized w eb data c lustering i nto two c lasses (I) u sers' s essions-based and (II) link-based. The former uses the web log data and tries to group together a set of users' n avigation s essions h aving s imilar characteristics. I n web log data provide information about activities performed by a u ser f rom t he m oment t he u ser enters a w eb s ite to the moment the same user leaves it. The records of users' actions within a web site are stored in a log file. Each record in the log file co ntains the cl ient's IP ad dress, the d ate and time the request is received, the requested obj ect and some a dditional information -such as protocol of request, size of the object etc [4].

Sarukkai et al. (2000) discovered e normous growth in the number of documents in the W WW i ncreases the n eed for improved link navigation and path analysis models. The author introduced lin k p rediction a nd p ath analysis are important problems with a w ide r ange of applications ranging f rom personalization to web server request prediction. The sheer size of the W WW coupled with the variation in us er's navigation patterns m akes t his a v ery d ifficult s equence m odeling problem. The author observed Markov chains allow the system to dynamically m odel the U RL acc ess p atterns. The M arkov chain m odel can a lso be used in a ge nerative m ode t o automatically o btain tours. The M arkov transition matrix c an be analyzed further using Eigen-vector decomposition to obtain

personalized hubs/authorities. The utility of the Markov chain approach is demonstrated in m any d omains: H TTP request prediction, s ystem d riven adaptive w eb na vigation, t our generation, and detection of personalized hubs/authorities from user navigation profiles. The generality and power of Markov chains is a first s tep t owards the a pplication of p owerful probabilistic models to web path a nalysis and link prediction [5].Khalil et al. (2007) introduced concept of prediction of the next page to be accessed by web users. This attracted a large amount of research work lately due to the positive impact of such prediction on different areas of web based applications. Major techniques applied for this intention are Markov model and clustering. Low order Markov models are coupled with low accuracy, high order Markov models are associated with high state space complexity. On the other hand, clustering methods are unsupervised methods, and normally are not used for classification directly. It involves incorporating clustering with low order Markov model techniques. The pre-processed data is divided into meaningful clusters then the clusters are used as training da ta w hile pe rforming 2<sup>nd</sup> order M arkov m odel techniques. Different distance measures of k-means clustering algorithm are examined in order to find an optimal one. The author revealed that incorporating clustering of web documents according t o Webs ervices with l ow or der M arkov m odel improves the web page prediction accuracy [6].

Deshpande e t a l. (2001) i ntroduced pr oblem of pr edicting a user's behavior on a web site has gained importance due to the rapid gr owth o f t he W orld W ide Web and the ne ed t o personalize an d i nfluences a u ser's browsing e xperience. Markov models and its variations found to be well suited for addressing t his problem. D ifferent va riations o f Markov models, it found that higher-order Markov models display high predictive accuracies on web sessions that it can predict. However, higher-order models are also extremely complex due to their large number of states, which increases their space and run-time requirements. T he author p resented d ifferent techniques for intelligently selecting p arts o f d ifferent or der Markov models so that the resulting model has a reduced state complexity, while maintaining a high predictive accuracy [7].

Zacharouli et al. (2009) introduced learning algorithms for web page r ank pr ediction, linear r egression models a nd combinations of r egression with pr obabilistic c lustering and Principal Components Analysis (PCA). These models learned from time-series data sets and can predict the ranking of a set of web pages in some future time. The algorithm used separate linear regression models. This further extended by applying probabilistic clustering based on the EM algorithm. Clustering allows for the web pages to be grouped together by a mixture of regression m odels. A different m ethod combined l inear regression with PCA so as dependencies between different web pages can be exploited. All the methods evaluated using real data s ets obtained f rom I nternet A rchive, Wikipedia a nd Yahoo! ranking lists. It also study the temporal robustness of the prediction framework. Overall the system constitutes a set of tools for high accuracy page rank prediction which can be used for efficient resource management by search engines [8].

Spiliopoulou e t al. (1999) investigated web s ite de sign is currently based on interests of web site visitors and assumptions a bout their e xact b ehavior. Concrete knowledge on the w ay vi sitors n avigate i n a web s ite could prevent disorientation a nd he lp owners i n placing i mportant information exactly where t he vi sitors l ook f or it. Web utilization miner tool can provide such knowledge. The general problem a ddressed is gi ven a num ber of t raversed pa ths discovers s ub-paths w ith s tructural or s tatistical p roperties of interest. All nodes in a sub-path are of equal Importance. Subpaths having only some nodes in common be combined into a pattern that shows the desired properties as a whole to capture the ambiguous e xpressions of t his p roblem. T he a uthor described a powerful mining language by which the expert can specify th e d esired s tructural a nd s tatistical properties of the patterns. To efficiently d iscover paths which when c ombined result in such desirable patterns, an innovative technique based on the processing of aggregated sequence several optimization steps are performed to further reduce the mining search space [9].

Mukhopadhyay e t a l. (2011) s tudied about pre-fetching models based on d ecision t rees, M arkov chains, an d p ath analysis. The author described increase uses of dynamic pages, frequent changes in site structure and user access patterns have limited th e e fficacy o f these s tatic t echniques. O ne of the techniques that are used for improving user latency is Caching and another is W eb pre-fetching. A pproaches that bank solely on caching offer limited performance improvement because it is d ifficult f or caching t o ha ndle t he large num ber o f increasingly diverse files. An agent based method is proposed here to cluster related pages into different categories based on the access patterns. Additionally page ranking is used to build up the prediction model at the initial stages when users are yet to invoke any page [10].

Kumar et al. (2011) pr esented web pr ovides a c orpus of design e xamples unpa ralleled i n hum an hi story. L everaging existing designs to produce new pages is difficult. The author introduced the Bricolage algorithm f or automatically transferring design and content between Web pages. Bricolage introduces a novel structured prediction technique that learns to create coherent mappings between pages by training on human-generated exemplars. The produced mappings can then be used to au tomatically transfer the content f rom o ne page i nto t he style and l ayout of another. The author shown that Bricolage can learn to accurately reproduce human p age mappings, and that it provides a general, efficient, and automatic technique for retargeting content between a variety of real web pages [11].

Dutta et al. (2011) studied web p age pr ediction p lays an important role by predicting and fetching probable web page of next request in advance, resulting in reducing the user latency. The users surf the internet either by entering URL or search for some topic or through link of same topic. For searching and for link pr ediction, c lustering plays a n i mportant role. Web page prediction model give us significant importance to the user's interest us ing t he c lustering t echnique and the na vigational behavior of t he us er through M arkov m odel. The c lustering technique i s us ed f or the a ccumulation o f t he s imilar w eb pages. S imilar web pages of s ame t ype r eside in the s ame cluster, the cluster containing web pages have the similarity with respect to topic of the session. The clustering algorithms considered are K-means and K-mediods, K is determined by HITS algorithm. Finally, the predicted web pages are stored in form of c ellular au tomata t o make t he s ystem more me mory efficient [12].

Su et al. (2000) studied the rapid development of internet has resulted in more and more multimedia in web content. The author studied due to the limitation in the bandwidth and huge size of the multimedia data, users always suffer from long time waiting. The author describe that to predict the web object or page that the user most likely will view next while the user is viewing the current page, and pre-fetch the content. Then the perceived n etwork latency can be significantly reduced. The author introduced n-gram based model to utilize path profiles of us ers from very l arge web l og t o predict the us ers' future requests. Model i s based o n a s imple e xtension o f e xisting point-based models for such predictions, but results show that by sacrificing the applicability somewhat one can gain a great deal in pr ediction pr ecision. T he r esults c an potentially b e applied to a wide range of applications on the web, including pre-fetching, enhancement of recommendation systems as well as web ca ching p olicies. T he experiments b ased o n t hree realistic web logs have proved the effectiveness of the proposed scheme [13].

Zukerman et al. (2009) used Artificial Intelligence-related techniques to pr edict user r equests. T he author i mplement a learning a lgorithm such as some variation of M arkov chains and use a previous access log in order to train it. This approach also relies on tracking user patterns. Furthermore, it does not handle newly introduced pages, or old pages that have changed substantially. T his approach also r equires a r ather long sequence of clicks from a user to learn his/her access patterns [14].

Safronov et al. (2010) introduced the Page Rank based prefetching technique which is a server-side approach and uses the information about the link structure of the pages and the current and p ast user accesses to drive pre-fetching. The approach is effective for access to web page clusters, is computationally efficient and scalable, and can immediately sense and react to changes in the link structure of web pages. Furthermore, the underlying a lgorithm u ses relatively simple matrix operations and is easily p arallelizable, making it s uitable f or c lustered server environments [15].

Padmanabhan et al. (1995) investigated ways of optimizing retrieval latency. W eb ca ching has been r ecognized as an effective solution to minimize user access latency. A method of called pre-fetching introduced in which clients in collaboration with server pre-fetch web page that the user is likely to access soon, v iewing the cu rrently d isplayed page 1. The benefit of pre-fetching is to provide low retrieval latency for users, which can be explained as high hit ratio. This approach reduces web latency b y p re-fetching be tween caching, p roxies, and browsers. Web pre-fetching has involved the important issue of log file processing and the determination of user transactions (sessions). It pr ovides various data mining a lgorithms for the path traversal patterns and how to efficiently mine the access patterns from the web logs [16].

# 3. PROPOSED MODEL

Web page is the integration of the different web page contains frames, graphics and other information. User cache is used in this model to cache the frequently accessed web page. In the proposed model, wer equest the certain web page from the server then server will send the URL of that web page to the predictor. After that predictor check the required specific web page, if it is present then predictor gives that web page to the server and server also give required page to the client to meet its r equirements. But the predictor while sending the page to the server (in case the predictor is n ot a ble t o ch eck t he requested web page), also give the client's requested web page to the u pdate e ngine f or upd ate a nd a lteration of the data structure. T he use o f p redictor i n the process of web page anticipation is that it uses the data structure for storing the web pages. [17]

## 3.1 FLOW CHART OF REQUIRED MODEL

The following flow chart presents the required model and the requisite steps to implement the required Markov model, which in turn helps in web page anticipation. In the proposed model, first step is to give input with the help of preprocessing the web server log files, after which similar web sessions are allocated to ap propriate ca tegories. By us ing clustering, we de cide the number of clusters and among these clusters web sessions are partitioned. The process of c lustering gives us the c lustered data which is used for the Markov model approach.

When the M arkov m odel is applied we have d ecide the prediction algorithm and then apply the hidden Markov model in prediction algorithm. After the d etermination of the prediction a lgorithm the next web page f or us er a ccess i s available as output.

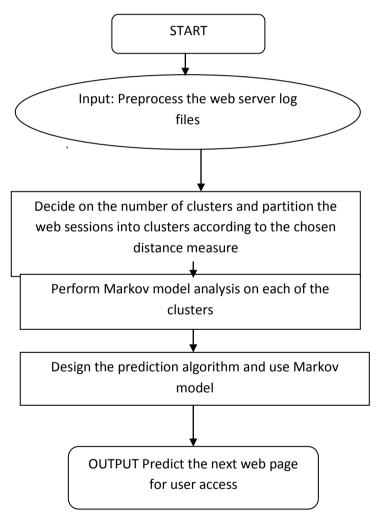

Figure2. flow chart for web page anticipation

## 1. STEP1:

web s erver l og f iles are preprocessed i n a w ay s imilar web sessions are allocated to appropriate categories.

#### 2. STEP2:

Convert t he w eb pages i nto n umeric f orm an d s tore i n web.dat file and then determine the number of clusters and then

division of web sessions into clusters is done using clustering tool based on FCM algorithm on Matlab.

The FCM Algorithm uses the k-means clustering to choose the number of clusters k. In this clusters centers U1 to Uk are decided after that we could pick k data points and set cluster centers t o t hese points or it could r andomly a ssign po ints t o clusters and t ake means of c lusters. For each data point, we decide the cluster center it is closest to and assign the data point to this cluster.

After t hat with t he he lp of findcluster c ommand on the command prompt on the matlab, the web.dat file is loaded on Matlab.

### 3. STEP3:

Perform M arkov m odel analysis on e ach of the c lusters and then m ake s quared Transition probability m atrix and s quared Emission Probability Matrix.

Making o f squared T ransition P robability Matrix (Rows=Columns=Total number o f unique web pa ges=9) TRANSITION (I,J) is the probability of transition from state I to state J

Making of s quared E mission P robability M atrix (Rows=Columns=Total num ber of uni que w eb pages=9) EMISSION(K,L) is the probability of transition from state K to L.

#### 4. STEP4:

Design t he prediction a lgorithm and us e hi dden Markov Model approach. This algorithm gives us information about the next page with the help of user's currently accessed web page.

# ALGORITHM:-

1. Set T r=Transition square matrix, Tr(I,J)=Probability of transition from state I to state J. [Initializes Tr]

2. Set E=Transition square matrix, Tr(K,L)=Probability of transition from state K to state L. [Initialize E]

3. Set seq=sequence of user's accessed web page. [Initialize seq]

4. numStates= number of states and size=size of any column Tr.

numStates=size

5. L=length of seq

6. Repeat for count 1 To L

- 7. Repeat for state 1 to numStates
- 8. Set bestVal=0 [initialize bestVal]

9. Set bestPTR=0 [initialize bestPTR]

10. Repeat for inner 1to numstaes

Val=Tr[innerstate]

If val> bestVal

bestVal=val

bestPTR=val

bestPTR= inner

[End of if structure]

[End of step 10 inner loop]

- 11. PTR[state,count]=bestPTR
- 12. v[state]=E[state,seq[count]]+ bestval [End of 7 inner loop]

13 ..vOld=v

- 14. P=max[v] max is maximum value
- 15. finalState= max[v]
- 16. currentState[count]=finalState

[End of step 6 outer loop]

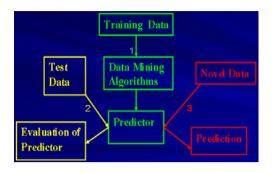

Figure 3. Prediction Architecture for training Data

#### 5. STEP 5:

If we execute this prediction algorithm on the matlab then this will g ive a next pr obable webpage f or us er's currently accesses webpage.

# 4. RESULTS

Merging w eb pages by w eb s ervices a ccording t o t heir function in t urn reduces t he nu mber o f uni que pa ges. The sessions w ere di vided i nto varying c lusters us ing k -means algorithm and cosine function measure. For each cluster, the categories were expanded back to their original form in the data set. This process is performed using a simple program that seeks and displays the data related to each category. Markov model implementation was carried out for the clusters. Markov model a ccuracy was calculated a ccordingly. Then, u sing the test s et, e ach t ransaction w as c onsidered a s a new po int a nd distance measures were calculated in order to define the cluster that the point be longs to. Markov model prediction a ccuracy was computed considering the transaction as a test set and only the c luster t hat the t ransaction be longs t o a s a t raining s et. Prediction accuracy results were achieved using the maximum likelihood based on conditional probabilities.

All implementations were carried out using MATLAB. The Markov model accuracy was calculated using a 10-fold cross validation. Results collected are user's currently accessed web page and N ext web page f or u ser's cu rrently accessed web page. The reported accuracy is the how many Next web pages are user's actually accessed web pages after user's currently accessed web pages. Markov model accuracy u sing cl usters based on Cosine distance measures with k = 4.

All clustering runs have performed on a desktop PC with a Pentium IV Intel processor r unning at 2 G Hz with 2 G B of RAM and 100 GB of hard disk memory. The runtime of the kmeans algorithm, r egardless of the distance measure used, is equivalent to O(nkl), n is the number of items, k is the number of clusters and l is the number of iterations t aken b y the algorithm to converge. For experiments, n and k are fixed, the algorithm has a linear time complexity in terms of the size of the da ta set. The k-means a lgorithm has a O(k + n) space complexity. This is because it requires space to store the data matrix. It is feasible to s tore the data matrix in a secondary memory and then the space complexity will become O(k). k-means al gorithm is more time and s pace of ficient t han hierarchical c lustering a lgorithms with  $O(n^2 \ logn)$  time complexity and  $O(n^2)$  space complexity.

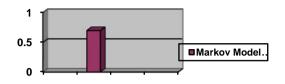

Figure 4. Markov Model accuracy

#### **5.CONCLUSION**

This p aper d escribes the o verall p rediction accuracy by grouping the data set sessions into clusters and reduces the web latency time. The web pages in the user sessions are segregated into categories according to Web services that are functionally meaningful. Then k-means clustering algorithm is implemented using the most appropriate number of clusters. The Prediction algorithm for the determination of us er's next probable page with the help of user's currently accessed page is applied on the number of c lusters. The r esults gives us the a ccuracy of the next page access p rediction by i mplementing t he k -means clustering algorithm on the data set decided previously. More accuracy describes most accurate web page predicted with the help of prediction algorithm implementation as user want next time. Now us er do not ne ed to request the web page as us er wants, because it has been available before the time user want it next time. In this way we are able to utilize the minimum bandwidth of the user and the use of pre-fetching and clustering reduces the request made by user and reduces request time. The prediction a ccuracy achieved is an improvement over the problems o ccurred to the us er at the time of accessing web information on the Internet.

# 6. FUTURE WORK

This p aper in troduced th e Prediction a lgorithm f or automatically transferring W eb pages. It demonstrated that it can learn to closely reproduce human mappings, and it take a one step towards a powerful new paradigm for instance- web based de sign a nd opens up ex citing ar eas for r esearch. A t present, the algorithm employs only about thirty simple visual and s emantic f eatures. E xpanding t his s et to include m ore complex and sophisticated properties, s uch as those based on computer v ision, w ill lik ely im prove the robustness of t he machine le arning. A dditionally, th is im plementation cannot handle idiosyncrasies of modern HTML. Extending Prediction to these technologies remains future work.
